

Building digital products with AI tools

A hands-on course for beginners and non-technical professionals

6 sessions

one tool per session

1.5 months

every Saturday

2.5–3 hours

per session

No theory

practice only

One project

built from session one

About the course

The course is built on one principle: every Saturday means one tool, live exercises and a finished artefact. No slides for the sake of slides. By the end of every session, each participant has something that actually works.

Who it's for

- Non-technical professionals: product managers, designers, marketers, entrepreneurs
- People with a product idea but no time to learn programming from scratch
- Anyone who wants to stop depending on developers to build prototypes

Format

- 6 Saturday sessions of 2.5–3 hours
- A group of 8–12 people: big enough for good dynamics, small enough for individual help
- Every participant builds their own product from the first session
- Mentor chat between sessions, with expert feedback on homework
- Demo Day at the end: everyone shows a live application

What you will be able to do

Build an MVP with AI tools, without writing code yourself

Write clear prompts and specs for an AI agent

Set up and use an agentic development environment

Keep code under version control with GitHub

Connect a local or cloud database

Put an app online with sign-in and access control

Create autonomous AI agents with their own skills and roles

Use AI tools safely

Understand where AI fits in the software development lifecycle

You will need: a laptop and a subscription to the main tool, Claude or Codex (about \$20 per month).

Programme

01 First steps: from a spec to a working prototype

[VS Code](#) [Codex](#)

Outcome: a configured agentic development environment and a first working prototype, built without writing code.

- How the course works; key terms: IDE, stack, agent, database, webhook, API
- Installing and setting up VS Code: the main elements, plugins, signing in, the project folder
- How to write a development spec for an AI agent
- Hands-on: write your spec and build a working prototype, with a separate room for questions
- Review of results and Q&A
- Homework: a prototype running in your IDE. The core principle: delegate everything to the agent. Tip: start using voice input with your agent

02 Managing code: versions and documentation

[GitHub](#)

Outcome: your project under version control, with changes pushed to GitHub.

- Why version control matters, even when an agent writes the code
- Keeping project documentation up to date

03 Connecting a database

[Key-value store](#) [SQLite](#) [Supabase](#)

Outcome: a cloud database with row-level security and realtime updates.

- Overview of database types, queues and message brokers, and basic architecture
- Why we start with a key-value store and a local SQLite, then move to the cloud

04 Putting your app online

[Vercel](#) [Supabase Auth](#)

Outcome: a production deployment with user sign-in.

- Deploying to Vercel and adding authentication
- An alternative: deploying to regular hosting, all done through the agent

05 Personalising your AI agent

[Claude Code](#) [skill.md](#) [CLAUDE.md](#)

Outcome: your own agent with skills, roles and project instructions.

- Autonomous AI agents, running locally or in the cloud
- Agent skills and roles, and chaining agents together

06 Demo Day and wrap-up

[Demo Day](#) [Bonus: VPS / Docker](#)

Outcome: every participant presents a live application.

- Demos, feedback and next steps
- Bonus topic: deploying to your own server with a VPS and Docker

Across the course: safe use of AI tools and AI in the software development lifecycle, regardless of the tool.
